

Well, first of all there are  $0.15 \text{ V}^\circ\text{C}$  produced by the measurement, so the output of the measurement is  $0.15T \text{ V}$ . Second, the differential amplifier will subtract  $3 \text{ V}$  (the setpoint) and then amplify the result by 10 (ten). Thus the input to the diodes and the relays is:

$$V_D = 10(0.15T - 3)$$

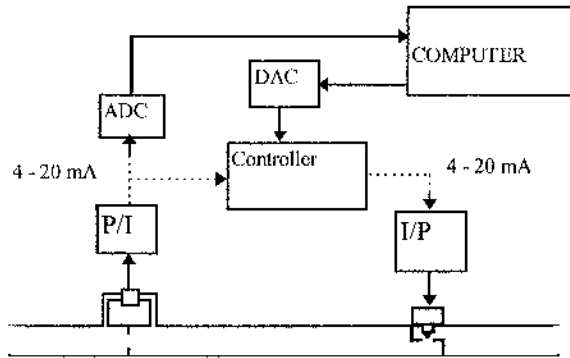

or, solving for  $T$ , since that is what we want to find,

$$T = (3 + V_D/10)/0.15$$

If we assume ideal diodes with no forward voltage drop, then the temperatures can be found from the above equation by setting  $V_D$  equal to  $+1.5 \text{ V}$ ,  $+1.1 \text{ V}$ ,  $-1.1 \text{ V}$ , and  $-1.5 \text{ V}$  and solving for  $T$  in each case.

- +1.5 V: cooler on,  $T = (3 + 1.5/10)/.15 = 21 \text{ }^\circ\text{C}$
- +1.1 V: cooler off,  $T = (3 + 1.1/10)/.15 = 20.7 \text{ }^\circ\text{C}$
- 1.1 V: heater off,  $T = (3 - 1.1/10)/.15 = 19.3 \text{ }^\circ\text{C}$
- 1.5 V: heater on,  $T = (3 - 1.5/10)/.15 = 19 \text{ }^\circ\text{C}$

1.12 For Supervisory Control:

For Computer Control:

1.13

First of all we need a manual valve on the cold water, a temperature sensor on the mixed hot and cold water and a temperature readout. Then on the hot water side we need a control system to regulate the hot water valve. The system block diagram for analog and digital control is shown in the following diagrams: (a) analog
